Abstract

Malaria is a major public health problem especially in tropical and sub-tropical regions around the world with varied hematological consequences. Thrombocytopenia is common in the laboratory finding among patients with malaria. Mechanism of thrombocytopenia in malaria is till now not clearly known. In this review we try to evaluate the presence of thrombocytopenia during malaria as valuable Indicator tool for presence of Malaria.

Keywords: Thrombocytopenia; Malaria; Low Platelets

1. Introduction

Malaria continues to be a major health problem in more than 100 endemic countries located primarily in tropical and sub-tropical regions around the world [1]. Malaria is a severe disease caused by parasites of the genus Plasmodium, which is transmitted to humans by a bite of an infected female mosquito of the species Anopheles. Malaria remains the leading cause of mortality around the world, and early diagnosis and fast-acting treatment prevent unwanted outcomes [2]. Hematological changes are some of the most common complications in malaria and they play a major role in malaria pathogenesis. Patients infected with malaria exhibited important changes in most of hematological parameters with low platelet, WBCs, and lymphocyte counts being the most important predictors of malaria infection [3]. Alterations of blood coagulation are thought to be involved in malaria pathogenesis. Also, in malaria patients without clinically evident bleeding or thrombotic complications, alterations of the blood coagulation system, such as decreased levels of plasma antithrombin or elevated levels of plasminogen activator inhibitor (PAI)-1, and thrombocytopenia are frequently found [1,5,6].

Most of researchers reported that, Anemia thrombocytopenia are the most frequent malaria-associated hematological complications and have received more attention in the scientific literature due to their associated mortality [7,8]. The anemia is usually due to varied reasons ranging from hemolysis to comorbidities like parasitic infections, folate, iron, and vitamin B12 deficiencies in endemic areas, antimalarials and further complicated by the coexistence of thalassemia and other haemoglobinopathies [9,10]. Regarding to thrombocytopenia during malaria however is yet to be understood clearly and what the mechanism exactly leads to lower the number of thrombocytes during malaria, some researchers hypothesize that malaria parasite produces factors that reduce the platelet production from the megakaryocytes. This saves the parasite from the platelet mediated clearance as a survival mechanism [11]. Other studies reported the mechanisms leading to thrombocytopenia are coagulation disturbances, splenomegaly, bone marrow alterations, antibody-mediated platelet destruction, oxidative stress, and the role of platelets as cofactors in triggering severe malaria [9,12,13,14,15]. Fajardo and Tallent demonstrated Plasmodium vivax within platelets by electron microscopy and suggested a direct lytic effect of the parasite on the platelets [16]. Multiple studies indicate that platelets appear to both ameliorate infection by killing parasites and compromise the host by mediating adhesion of infected erythrocytes to the vascular wall. Herein, the possible causes of malaria-induced thrombocytopenia as well as the roles of the platelets in the erythrocytic stage of the disease will be discussed [17]. Another study conducted by Steven Kho et al.,
demonstrates the direct pathogen-killing actions and host protective roles of platelets during human malarial infection. Given platelets show broad-spectrum antimicrobial activity, and the risks for infection associated with thrombocytopenia [18]. Another hypothesis released by R. Conte et al., that autoantibodies against platelet glycoproteins IIb–IIIa and Ia–IIa might be present during malaria and could lead to severe thrombocytopenia [19]. Lee SH et al., conducted clinical trial in plasma macrophage colony-stimulating factor and P-selectin levels in malaria and they suggest that elevated M-CSF in malaria, by enhancing macrophage activity, may result in increased macrophage-mediated platelet destruction [20]. Another study conducted by Casals et al., in Kenya about thrombocytopenia among patients with falciparum malaria and find thrombocytopenia strongly correlates with high levels of interleukin (IL)-10 [21]. Kotepui et al., observed patients during infected with malaria exhibited important changes in most of hematological parameters with low platelet, WBCs, and lymphocyte counts being the most important predictors of malaria infection. When used in combination with other clinical and microscopy methods, these parameters could improve malaria diagnosis and treatment [22].

2. Conclusion

Malaria is associated with different degrees of low platelet count generally mild or moderate and bleeding is rare even during severe malaria. Thrombocytopenia can used as indicator value for presence of malaria after excluding others causes. The relationship between thrombocytopenia and malaria not sufficiently understood till now. Further evaluation of thrombocytopenia should be undertaken during malaria.
