Abstract

Analgesic is any drug used to achieve analgesia—relieve from pain, without blocking the conduction of nerve impulses. Sukun (*Artocarpus altilis*) and melinjo (*Gnetum gnemon* L.) are plants that can be expected to have analgesic properties because they contain bioactive that can inhibit biosynthesis of prostaglandins, a hormone-like pain reducing agent. To determine analgesic effect of two plants in question, the combination extract of melinjo and sukun leaves were treated to mice by applying writhing test. Male mice (n=28) were grouped into seven consisted of two control groups (negative dan positive) and five test groups. The negative control group (KN) received CMC 0.5%, the positive control mice received 1.3 mg/kg BW mefenamic acid. Test groups were given leaf extracts of sukun and melinjo with the dose ratios (sukun : melinjo) as follows (200: 0), (150 : 50), (100 : 100), (50 : 150), and (0 : 200) mg/kg BW respectively. After 15 minutes all mice were pain-induced with 1% acetic acid intraperitoneally. Stretching activity of the animals was observed every 5 minutes for 1 hour. The result showed that the extracts with a dose ratio of (150 + 50) mg/kg BW has a comparable analgesic effects to the mefenamic acid is the most effective combination among other combination doses.

Keywords: Analgesic drug; Melinjo; *Gnetum gnemon*; Sukun; *Artocarpus altilis*

1. Introduction

Health is very important for humans to achieve prosperity and happiness. One of the health problems that occur in humans is pain. Pain is a sensory and emotional feeling that is uncomfortable for the sufferer and pain occurs as a sign of tissue damage. Pain is a symptom of disease caused by chemical or physical mechanical stimulation that exceeds the pain threshold and causes tissue damage with the release of pain mediators such as histamine, bradykin, leukotrienes and prostaglandins [1].

There are various kinds of analgesic drugs commonly used by the public, both in the form of traditional and synthetic medicines. Some examples of analgesic drugs are paracetamol, aspirin, ibuprofen, and mefenamic acid. Long-term use of synthetic drugs can relieve pain, but not a few side effects. The most common side effects are gastrointestinal disorders, blood damage, liver and kidney damage and also allergic skin reactions [2, 3].

One of the plants used as traditional medicine is the melinjo plant (*Gnetum gnemon* L.). Melinjo plant has benefits in the field of traditional medicine such as shedding urine, curing eye diseases and anemia. This plant has many benefits because almost all of its parts, from flowers, fruit, stems and especially leaves. Melinjo leaves are known to contain saponins, tannins and flavonoids. Related research that has been done previously is the analgesic activity of the ethanol

*Corresponding author: Mohammad Kanedi

extract of melinjo leaves (*Gnetum gnemon* L.) in male white mice which has analgetic power with a concentration of 51.84 mg / kg BW [4].

Another plant that has been empirically proven to be used as a pain reliever in toothache, canker sores, itching, joint pain, kidney disease, heart disease and diabetes is the sukun plant (*Artocarpus altilis*). Sukun leaves contain chemical substances, namely saponins, tannins, flavonoids. Previous research related to the analgesic activity of the ethanol extract of sukun leaves (*Artocarpus altilis*) against male white mice induced by acetic acid had analgetic power with concentrations of 100 mg/kg BW and 200 mg/kg BW [5, 6].

The problem with painkillers, especially those made from synthetic ingredients such as opioids, is the presence of various side effects such as: kidney disorders, drug dependence, or impaired infant development [7]. These facts encourage researchers stay to seek and develop any pain medication from natural sources that are safe with minimal side effects.

In an effort to find a safe analgesic drug, this research was conducted. The melinjo and sukun leaves are known to contain flavonoid compounds that are revealed to inhibit cyclooxygenase enzyme activity. Activity inhibition of the cyclooxygenase enzymes theoretically will decrease the production of prostaglandins and reduces pain [8]. But, given the previous data revealed that the leaf extracts of sukun and melinjo showed different analgesic activity, so in this study we combined the extracts of the two plants.

2. Material and methods

2.1. Plant materials and extraction

The plant leaf samples of the sukun (*Artocarpus altilis*) and melinjo (*Gnetum gnemon* L.) were collected from the village of Kalidadi Kalirejo District, Central Lampung Regency, Lampung Province, Indonesia. Taxonomic determination of the plant was carried out by plant taxonomist at the Botanical Laboratory, Department of Biology, Faculty of Mathematics and Natural Sciences, University of Lampung, Indonesia.

The fresh leaves of the plants were washed and rinsed using running tap water to remove all dirt and impurities. Next, the leaves were chopped into small pieces and then sun-dried under a black cloth cover. The use of a black cloth is intended to prevent the sample from being exposed to UV rays. The dried chopped leaves (400 g) are macerated using 70% ethanol in a dark glass container. The filtrate were collected by filtration after 24 hours. The solid residues were then re-macerated using the same solvent every 24 hours until the extract is completely clear. Furthermore, the obtained filtrate is evaporated using a rotary evaporator until a viscous extract of melinjo and sukun leaves are obtained.

2.2. Preparation of the test ingredient

In this study, all materials given to mice mefenamic acid and ethanol extract of melinjo and sukun leaves were suspended in 0.5% CMC (w/v). A total of 0.5 g CMC was sprinkled into the mortar containing 10 ml of distilled water that had been heated and crushed until homogeneous. The homogenous suspension transferred into measuring flask and then distilled water is added up to 100 mL of volume. Mefenamic acid tablets (500 mg), the standard drug, were finely ground and in a mortar containing of 10 ml of 5% CMC.

There were seven different test ingredients prepared in this experiment, namely: vehicles as the negative control (KN); standard drug as positive control (KP); and five different extract dose combinations of sukun and melinjo leaves namely K1, K2, K3, K4, and K5

KN: Containing only vehicle, 0.5% CMC (w/v);

KP: Contains mefenamic acid at the doses of 1.3 mg/Kg BW;

K1: The test ingredients containing only sukun leaves extract of 200 mg/kg BW;

K2: Containing sukun leaves extract of 50 mg/kg and melinjo leaves extract 150 mg/kg BW;

K3: Containing sukun leaves extract of 100 mg/kg and melinjo leaves extract 100 mg/kg BW;

K4: Containing sukun leaves extract of 150 mg/kg and melinjo leaves extract 50 mg/kg BW;

K5: The test ingredients containing only melinjo leaves extract of 200 mg/kg BW.

2.3. Animals and experimental design

Male mice (n=28) with a weigh range of 20 – 30 g, obtained from Veterinary Centre Lampung, by applying completely randomized design were divided into seven experimental groups (4 mice each). The mice grouping were based on the

ingredients provided namely KN (negative control), KP (positive control), K1, K2, K3, K4, and K5. All mice were kept for one week to adjust laboratory environment, given pellets and water ad libitum. Before treatments all mice were fasted for 18 hours, but they still have access to drinking water.

2.4. The test protocol

Fifteen minutes after the mice received test ingredients, each group of the animals were given 1% acetic acid (v/v) to induce pain. Wriggling response of the mice was then observed every five minutes for 1 hour. The wriggling responses recorded in this experiment was SAP (Stretch attend posture), a body posture in which the mouse stretches forward and then retracts to its original position, pulls forward and backward their feet while the abdomen presses the floor without moving [9, 10]. Basing on the analgetic effect test data obtained, the percentage of protection and effectiveness of the test ingredients were determined using the following formula [11, 12].

$$\% \text{ Protection} = \frac{A-B}{A} \times 100\%$$

Where:

A = Mean number of stretches in negative controls

B = Average amount of stretches in positive control (test material)

$$\% \text{ Effectiveness} = \frac{\% \text{ Protection of a group}}{\% \text{ Protection of positive control}} \times 100\%$$

2.5. Phytochemical screening

To ensure that the breadfruit and melinjo extracts do contain bioactive compounds that have analgesic properties such as alkaloid, flavonoids, saponins, and tannins we conducted qualitative phytochemical screening tests. The presence of the alkaloids was determined using Wagner, Hager and Mayer's test. Tannin, saponin, steroid, and flavonoids were tested using Lead acetate and FeCl₃ test, Foam and Haemolysis tests, Salkowski test, Lead acetate test [13].

2.6. Data Analysis

The data obtained were analyzed using one way ANOVA with a confidence level of 95%. The Duncan test was applied in post hoc analysis.

3. Results and discussion

The analgesic effect of administering ingredients to the groups of test mice (KN, KP, K1, K2, K3, K4, K5) based on the wriggling response indicated by stretches activity of the animals is presented in Figure 1.

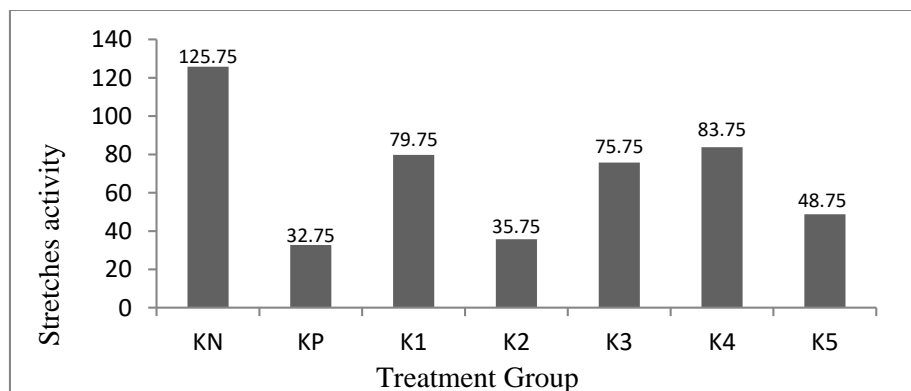

Figure 1 Mean number of stretches activity of mice after given treatments. KN= 0.5%CMC, KP: Mefenamic acid; K1=sukun extract of 200mg; K2= sukun:melinjo (50 :150)mg; K3= sukun:melinjo (100 :100)mg; K4= sukun:melinjo (150 : 50)mg; K5=melinjo extract of 200mg/Kg BW.

One way ANOVA test results showed a p -value of 0.000. This p -value indicates that the mean values of stretches activity among groups are significantly varied. The results of post hoc analysis using Duncan test can be described as follows. In comparison to the 0.5% CMC suspension (KN=negative control), all the dosage combinations of sukun and melinjo leaf extracts had a significant effect in reducing stretches activities in a dose-dependent manner.

Furthermore, when compared with standard drugs (KP=positive control) the extracts labeled as K2 and K5 did not show a significant difference in the number of mice stretches activity. These data suggest that the combined extracts of sukun and melinjo with a dose ratio of 50 : 150 mg/kg BW, and melinjo extract alone (200 mg/kg BW) have analgesic effects against acetic acid-induced pain in mice with similar efficacy with a conventional drug, mefenamic acid.

These data suggest that the combined extracts of sukun and melinjo with a dose ratio of 50 : 150 mg/kg BW, and melinjo extract alone (200 mg/kg BW) have analgesic effects against acetic acid-induced pain in mice with similar efficacy with a conventional drug, mefenamic acid.

The percentage of protection against pain and the percentage of effectiveness of the combined extract of sukun and melinjo leaves can be seen in Figure 2. These data confirm the analgesic effect of the sukun and melinjo leaf extracts as presented in Figure 1, that the extracts of sukun and melinjo with a dose combination of 50mg + 150mg (K2) and melinjo leaf extract alone at the dose of 200 mg/kg BW (K5) are the most providing protection against pain and are most effective.

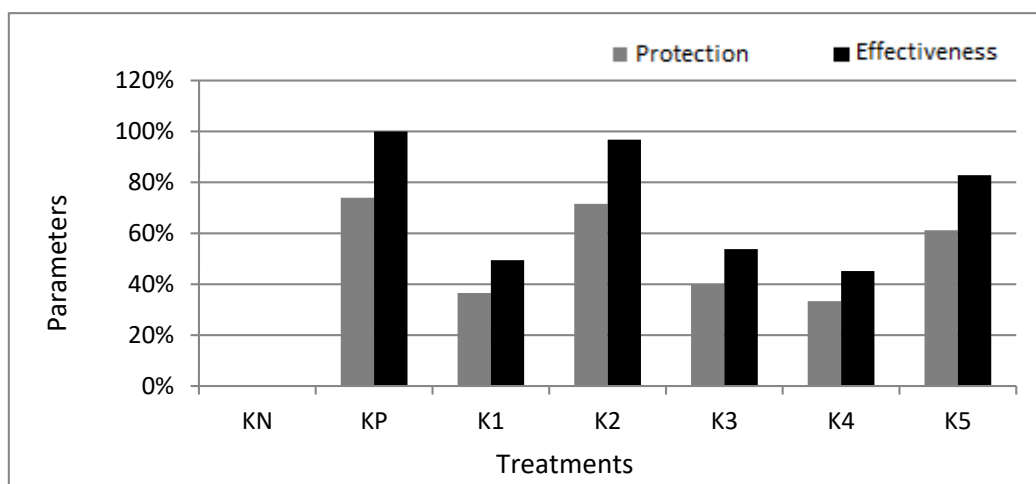

Figure 2 Percent protection and effectiveness of the extracts. KN= 0.5%CMC, KP: Mefenamic acid; K1=sukun extract of 200mg; K2= sukun:melinjo (50 :150)mg; K3= sukun:melinjo (100 :100)mg; K4= sukun:melinjo (150 : 50)mg; K5=melinjo extract of 200mg/Kg BW.

The results of qualitative determination of the phytochemicals content in the ethanol extract of sukun and melinjo leaves are presented in Table 1. Except for steroid/terpenoid, all phytochemicals previously known to have analgesic effects namely flavonoids, alkaloids, and tannins are present in the leaf extracts of sukun and melinjo.

Table 1 Phytochemicals that are detected in ethanol extract of sukun and melinjo leaves

Chemicals	Sukun leaves	Melinjo leaves
Alkaloid	(+)	(+)
Flavonoid	(+)	(+)
Saponin	(+)	(+)
Tanin	(+)	(+)
Steroid/Terpenoid	(-)	(-)

The results of this study can be summarized as follows. The ethanol extracts of sukun and melinjo leaves were revealed to have anti-pain (analgesic) activity. The percentage of protection and effectiveness of the combined leaf extracts of the two plants equaled the standard drug, mefenamic acid. Phytochemical compounds that are known to have analgesic properties, such as alkaloids, flavonoids, saponins, and tannins were identified in the ethanol leaf extract of the two plants.

With regard to the breadfruit plant (*Artocarpus altilis*), our findings appear to be somewhat different from previous reports. Pradhan et al., for example, failed to detect the presence of alkaloids and saponin in the petroleum ether, ethyl acetate, and methanol extract of sukun leaves. [14]. Similar results were also reported by Sikarwar et al. (2015) where the only confirmed phytochemicals were flavonoids, steroids, tannins [15]. Among the five bioactive compounds that are expected to have analgesic properties confirmed to be present in breadfruit leaf extracts by many phytochemical determination studies are flavonoids [16, 17].

Unlike the phytochemical content of breadfruit leaf extract, the phytochemicals that we found in the ethanol extract of melinjo leaves (*Gnetum gnemon* L.) were all confirmed by previous studies. Alkaloids, flavonoids, saponins, tannins and even the steroids were confirmed their presence in melinjo leaf extracts [18, 19].

The discrepancy in the results of phytochemical screening on sukun leaf extracts between previous studies and our findings may be due to differences in the solvents used in the extraction. Another possibility is that the content of alkaloids, saponins, tannins, and steroids in breadfruit leaves is too small. Whereas in the melinjo leaf extract the presence of these compounds is relatively high. This seems to be why the ingredients in K2 and K5 provide significant analgesic activity, closer to the standard drug. Both test ingredients, K2 and K5, contained a higher portion doses melinjo in comparison to the sukun. K2 contains melinjo extract with a combination dose of 150 mg of melinjo extract and 50 mg of sukun extract per kg BW, while K5 contains only melinjo extract at a dose of 200 mg/kg BW.

There are many types of plants that are reported to contain alkaloids, tannins, saponins which are thought to be used as analgesic and anti-inflammatory drugs such as *Anacardium occidentale* [20], *Globimetular brounii* [21], *Papaver libanoticum* [22].

The role of alkaloids, flavonoids, saponins, and tannins in providing analgesic and anti-inflammatory effects can be explained as follows. Alkaloids are thought to reduce pain by inhibiting the production of pro-inflammatory mediators such as IL-6, IL-1 β , iNOS, TNF- α , COX-2, and MIP-2. The inhibition of production of these pro-inflammatory compounds, particularly NO x , was reported by Borgi et al. from their experiments using *Zizyphus lotus* plant extracts [23], and by Bribe et al. from their experiment utilizing extracts of the *Fumaria capreolata* plant [24]. Tannins, on the other hand, exert analgesic effects by inhibiting the release of pro-inflammatory compounds, cytokines [25].

4. Conclusion

Breadfruit leaf ethanol extract, either separately or in combination, had an analgesic effect on acetic acid-induced mice. However, the highest percentage of protection and effectiveness is the combination of breadfruit and melinjo extracts with a dose ratio of 50 and 150 mg / kg BW, or melinjo leaf extract alone with a dose of 200 mg / kg BW. Thus, the combination of sukun (*Artocarpus altilis*) and melinjo (*Gnetum gnemon* L.) leaf extracts deserves to be recommended as an analgesic drug.
